

PERIODIC TABLE AND ELECTRON CONFIGURATION

15-16 year-olds

Rodrigo Alcaraz de la Osa. Translation: Rodrigo Alcaraz de la Osa and Alicia Sampedro (🐦 @AliciaInfoFyQ)

Electron Configuration

The **electron configuration** is the **distribution** of the **electrons** of an **atom** into **atomic orbitals** (s, p, d y f). **Möller's diagram** helps us to know the **order** in which the different **orbitals** should be **filled**, following the **arrows**.

Orbital	Shape	Maximum number of electrons
s		$2e^-$
p		$6e^-$
d		$10e^-$
f		$14e^-$

Möller's diagram. Adapted from https://commons.wikimedia.org/wiki/File:Diagrama_de_Configuraci%C3%B3n_electr%C3%B3nica.svg.

Ground state

State of **minimum energy**. Electrons *follow* **Möller's diagram**.

Excited state

Orbitals are not **filled** following **Möller's diagram**.

Forbidden state

Any **orbital** has **more electrons** than **allowed** $\left(\frac{s \ p \ d \ f}{2 \ 6 \ 10 \ 14}\right)$.

Valence Electrons

Valence electrons are those of the **outer shell** of an **atom**, being **responsible** for the **interactions** between **atoms** and the **formation** of chemical **bonds**.

Examples			
	GROUND (NEUTRAL)	GROUND (CATION)	EXCITED (NEUTRAL)
	$1s^2 2s^2 2p^6 \underline{3s^1}$ 1 valence e^-	$1s^2 \underline{2s^2 2p^6}$ 8 valence e^-	$1s^2 2s^2 2p^5 \underline{3s^2}$
	$1s^2 2s^2 2p^4 \underline{3s^3}$		
Sodium (Na)			

Periodic Table of Elements

The **periodic table of elements** arrange the **118 elements** known into **7 periods** (rows) and **18 groups** (columns), **order by its atomic number Z**.

GROUP		OUTER SHELL ELECTRONIC CONFIGURATION	VALENCE ELECTRONS
1		ns^1	1
2 (and He)		ns^2	2
13		ns^2np^1	3
14		ns^2np^2	4
15		ns^2np^3	5
16		ns^2np^4	6
17		ns^2np^5	7
18 (except He)		ns^2np^6	8

Classification of Chemical Elements

Chemical elements can be classified into **metals**, **metalloids**, **nonmetals** and **noble gases**, according to their **physical** and **chemical properties**:

Metals

Shiny appearance, they are **good conductors** of **heat** and **electricity** and they can make **alloys** with other metals. Most of them are **solids** at room T . (**Hg** is).

Ion formation They tend to **lose electrons**, forming **cations** (\oplus charged ions). **Examples**: $\text{Li} \rightarrow \text{Li}^+ + 1e^-$; $\text{Mg} \rightarrow \text{Mg}^{2+} + 2e^-$; $\text{Al} \rightarrow \text{Al}^{3+} + 3e^-$.

Metalloids

Breakable solids with a **metallic aspect** that are **semiconductors** and **behave like nonmetals**.

Nonmetals

Dull appearance, they are **bad conductors** of **heat** and **electricity** and they can be **breakable**. They can be **solids**, **liquids** or **gases** at room temperature.

Ion formation They tend to **gain electrons**, forming **anions** (\ominus charged ions). **Examples**: $\text{Cl} + 1e^- \rightarrow \text{Cl}^-$; $\text{O} + 2e^- \rightarrow \text{O}^{2-}$; $\text{P} + 3e^- \rightarrow \text{P}^{3-}$.

Noble gases

He, Ne, Ar, Kr, Xe and Rn. **Odourless and colorless monoatomic gases** which **barely react** chemically, since they have **eight electrons** in their **outer shell**.
